

AssistIQ – Step 1: Manual Ticket Intake (MVP)

1. Purpose of This Step

This document defines the **first implementation step** for AssistIQ: manually accepting ticket information copied from **Halo** and returning a suggested resolution.

This step deliberately avoids any API or direct integration with Halo to: - Reduce complexity - Eliminate security and data-leak risks - Focus on core value (resolution intelligence)

2. System Role (Very Important)

AssistIQ **is not a ticketing system**.

Halo remains the **system of record** for: - Ticket lifecycle - Status, SLA, ownership - Final resolution storage

AssistIQ acts as a **decision-support tool** only.

3. User Flow (Manual Intake)

1. IT staff opens a ticket in Halo
 2. IT staff copies relevant text from Halo
 3. IT staff pastes the text into AssistIQ
 4. AssistIQ analyzes the input
 5. AssistIQ suggests one or more possible resolutions
 6. IT staff:
 7. Uses the suggestion, or
 8. Provides a corrected / better resolution
 9. AssistIQ stores the feedback for future learning
-

4. Input Data (What the User Pastes)

For MVP, AssistIQ accepts **free text** only.

Typical content may include: - Ticket title - Problem description - Error messages / logs - System or environment name

No strict format is required in Phase 1.

5. Output (What AssistIQ Returns)

AssistIQ provides: - Suggested resolution steps - Confidence level (Low / Medium / High) - Source type: - Verified past solution - Knowledge article - Similar ticket

 AssistIQ **never auto-applies fixes**.

6. Feedback & Learning (Human-in-the-Loop)

After reviewing the suggestion, IT staff can:

-  Mark the suggestion as **Correct**
-  Submit a **Corrected / Improved Resolution**

When a corrected resolution is submitted: - It is stored as **human-verified knowledge** - It becomes eligible for future suggestions - No model retraining happens automatically

7. What Is Explicitly Out of Scope (Phase 1)

- Halo API integration
- Automatic ticket syncing
- Automatic ticket updates in Halo
- AI model fine-tuning
- User chat interface

These may be added in later phases.

8. Success Criteria for Step 1

This step is successful if: - IT staff can paste ticket text easily - AssistIQ returns a reasonable suggested resolution - Human feedback can be captured - Verified solutions improve future responses

9. Why This Design Is Intentional

This approach: - Matches real enterprise workflows - Minimizes risk - Enables controlled learning - Keeps AI explainable and auditable

10. MVP Flow Diagram (Manual Intake)

Below is the **end-to-end MVP flow** for AssistIQ using manual ticket intake from Halo.

Learning Storage
(Human-verified
solutions)

11. Key MVP Principles Illustrated

- Halo is **never modified** by AssistIQ
- AI only **suggests**, never applies fixes
- Humans are always in control
- Learning happens through **verified solutions**, not live retraining

12. What This Diagram Proves (Portfolio Value)

This MVP demonstrates: - Human-in-the-loop AI - Safe enterprise integration pattern - Clear system boundaries - Scalable foundation for automation later

13. Next Step After This Diagram

Design the **data model** that supports: - External ticket reference - AI suggestions - Human corrections - Verified solutions
